

CIVILIAN CASUALTIES

Justice in the Age of Big Data

The small city of Reading, Pennsylvania, has had a tough go of it in the postindustrial era. Nestled in the green hills fifty miles west of Philadelphia, Reading grew rich on railroads, steel, coal, and textiles. But in recent decades, with all of those industries in steep decline, the city has languished. By 2011, it had the highest poverty rate in the country, at 41.3 percent. (The following year, it was surpassed, if barely, by Detroit.) As the recession pummeled Reading's economy following the 2008 market crash, tax revenues fell, which led to a cut of forty-five officers in the police department—despite persistent crime.

Reading police chief William Heim had to figure out how to get the same or better policing out of a smaller force. So in 2013 he invested in crime prediction software made by PredPol, a Big Data start-up based in Santa Cruz, California. The program processed historical crime data and calculated, hour by hour, where crimes were most likely to occur. The Reading policemen could view the program's conclusions as a series of squares, each one just the size of two football fields. If they spent more time patrolling these squares, there was a good chance they would discourage crime. And

sure enough, a year later, Chief Heim announced that burglaries were down by 23 percent.

Predictive programs like PredPol are all the rage in budget-strapped police departments across the country. Departments from Atlanta to Los Angeles are deploying cops in the shifting squares and reporting falling crime rates. New York City uses a similar program, called CompStat. And Philadelphia police are using a local product called HunchLab that includes risk terrain analysis, which incorporates certain features, such as ATMs or convenience stores, that might attract crimes. Like those in the rest of the Big Data industry, the developers of crime prediction software are hurrying to incorporate any information that can boost the accuracy of their models.

If you think about it, hot-spot predictors are similar to the shifting defensive models in baseball that we discussed earlier. Those systems look at the history of each player's hits and then position fielders where the ball is most likely to travel. Crime prediction software carries out similar analysis, positioning cops where crimes appear most likely to occur. Both types of models optimize resources. But a number of the crime prediction models are more sophisticated, because they predict progressions that could lead to waves of crime. PredPol, for example, is based on seismic software: it looks at a crime in one area, incorporates it into historical patterns, and predicts when and where it might occur next. (One simple correlation it has found: if burglars hit your next-door neighbor's house, batten down the hatches.)

Predictive crime models like PredPol have their virtues. Unlike the crime-stoppers in Steven Spielberg's dystopian movie *Minority Report* (and some ominous real-life initiatives, which we'll get to shortly), the cops don't track down people before they commit crimes. Jeffrey Brantingham, the UCLA anthropology professor who founded PredPol, stressed to me that the model is blind to race and ethnicity. And unlike other programs, including the recidivism risk models we discussed, which are used for sentencing guidelines, PredPol doesn't focus on the individual. Instead, it targets geography. The key inputs are the type and location of each crime and when it occurred. That seems fair enough. And if cops spend more time in the high-risk zones, foiling burglars and car thieves,

there's good reason to believe that the community benefits.

But most crimes aren't as serious as burglary and grand theft auto, and that is where serious problems emerge. When police set up their PredPol system, they have a choice. They can focus exclusively on so-called Part 1 crimes. These are the violent crimes, including homicide, arson, and assault, which are usually reported to them. But they can also broaden the focus by including Part 2 crimes, including vagrancy, aggressive panhandling, and selling and consuming small quantities of drugs. Many of these "nuisance" crimes would go unrecorded if a cop weren't there to see them.

These nuisance crimes are endemic to many impoverished neighborhoods. In some places police call them antisocial behavior, or ASB. Unfortunately, including them in the model threatens to skew the analysis. Once the nuisance data flows into a predictive model, more police are drawn into those neighborhoods, where they're more likely to arrest more people. After all, even if their objective is to stop burglaries, murders, and rape, they're bound to have slow periods. It's the nature of patrolling. And if a patrolling cop sees a couple of kids who look no older than sixteen guzzling from a bottle in a brown bag, he stops them. These types of low-level crimes populate their models with more and more dots, and the models send the cops back to the same neighborhood.

This creates a pernicious feedback loop. The policing itself spawns new data, which justifies more policing. And our prisons fill up with hundreds of thousands of people found guilty of victimless crimes. Most of them come from impoverished neighborhoods, and most are black or Hispanic. So even if a model is color blind, the result of it is anything but. In our largely segregated cities, geography is a highly effective proxy for race.

If the purpose of the models is to prevent serious crimes, you might ask why nuisance crimes are tracked at all. The answer is that the link between antisocial behavior and crime has been an article of faith since 1982, when a criminologist named George Kelling teamed up with a public policy expert, James Q. Wilson, to write a seminal article in the *Atlantic Monthly* on so-called broken-windows policing. The idea was that low-level crimes and misdemeanors created an atmosphere of disorder in a neighborhood. This scared law-abiding citizens away. The dark and

empty streets they left behind were breeding grounds for serious crime. The antidote was for society to resist the spread of disorder. This included fixing broken windows, cleaning up graffiti-covered subway cars, and taking steps to discourage nuisance crimes.

This thinking led in the 1990s to zero-tolerance campaigns, most famously in New York City. Cops would arrest kids for jumping the subway turnstiles. They'd apprehend people caught sharing a single joint and rumble them around the city in a paddy wagon for hours before eventually booking them. Some credited these energetic campaigns for dramatic falls in violent crimes. Others disagreed. The authors of the bestselling book *Freakonomics* went so far as to correlate the drop in crime to the legalization of abortion in the 1970s. And plenty of other theories also surfaced, ranging from the falling rates of crack cocaine addiction to the booming 1990s economy. In any case, the zero-tolerance movement gained broad support, and the criminal justice system sent millions of mostly young minority men to prison, many of them for minor offenses.

But zero tolerance actually had very little to do with Kelling and Wilson's "broken-windows" thesis. Their case study focused on what appeared to be a successful policing initiative in Newark, New Jersey. Cops who walked the beat there, according to the program, were supposed to be *highly* tolerant. Their job was to adjust to the neighborhood's own standards of order and to help uphold them. Standards varied from one part of the city to another. In one neighborhood, it might mean that drunks had to keep their bottles in bags and avoid major streets but that side streets were okay. Addicts could sit on stoops but not lie down. The idea was only to make sure the standards didn't fall. The cops, in this scheme, were helping a neighborhood maintain its own order but not imposing their own.

You might think I'm straying a bit from PredPol, mathematics, and WMDs. But each policing approach, from broken windows to zero tolerance, represents a model. Just like my meal planning or the U.S. News Top College ranking, each crime-fighting model calls for certain input data, followed by a series of responses, and each is calibrated to achieve an objective. It's important to look at policing this way, because these mathematical models now dominate law enforcement. And some of them are WMDs.

That said, we can understand why police departments would choose to include nuisance data. Raised on the orthodoxy of zero tolerance, many have little more reason to doubt the link between small crimes and big ones than the correlation between smoke and fire. When police in the British city of Kent tried out PredPol, in 2013, they incorporated nuisance crime data into their model. It seemed to work. They found that the PredPol squares were ten times as efficient as random patrolling and twice as precise as analysis delivered by police intelligence. And what type of crimes did the model best predict? Nuisance crimes. This makes all the sense in the world. A drunk will pee on the same wall, day in and day out, and a junkie will stretch out on the same park bench, while a car thief or a burglar will move about, working hard to anticipate the movements of police.

Even as police chiefs stress the battle against violent crime, it would take remarkable restraint not to let loads of nuisance data flow into their predictive models. More data, it's easy to believe, is better data. While a model focusing only on violent crimes might produce a sparse constellation on the screen, the inclusion of nuisance data would create a fuller and more vivid portrait of lawlessness in the city.

And in most jurisdictions, sadly, such a crime map would track poverty. The high number of arrests in those areas would do nothing but confirm the broadly shared thesis of society's middle and upper classes: that poor people are responsible for their own shortcomings and commit most of a city's crimes.

But what if police looked for different kinds of crimes? That may sound counterintuitive, because most of us, including the police, view crime as a pyramid. At the top is homicide. It's followed by rape and assault, which are more common, and then shoplifting, petty fraud, and even parking violations, which happen all the time. Prioritizing the crimes at the top of the pyramid makes sense. Minimizing violent crime, most would agree, is and should be a central part of a police force's mission.

But how about crimes far removed from the boxes on the PredPol maps, the ones carried out by the rich? In the 2000s, the kings of finance threw themselves a lavish party. They lied, they bet billions against their own customers, they committed fraud and paid off

rating agencies. Enormous crimes were committed there, and the result devastated the global economy for the best part of five years. Millions of people lost their homes, jobs, and health care.

We have every reason to believe that more such crimes are occurring in finance right now. If we've learned anything, it's that the driving goal of the finance world is to make a huge profit, the bigger the better, and that anything resembling self-regulation is worthless. Thanks largely to the industry's wealth and powerful lobbies, finance is underpoliced.

Just imagine if police enforced their zero-tolerance strategy in finance. They would arrest people for even the slightest infraction, whether it was chiseling investors on 401ks, providing misleading guidance, or committing petty frauds. Perhaps SWAT teams would descend on Greenwich, Connecticut. They'd go undercover in the taverns around Chicago's Mercantile Exchange.

Not likely, of course. The cops don't have the expertise for that kind of work. Everything about their jobs, from their training to their bullet-proof vests, is adapted to the mean streets. Clamping down on white-collar crime would require people with different tools and skills. The small and underfunded teams who handle that work, from the FBI to investigators at the Securities and Exchange Commission, have learned through the decades that bankers are virtually invulnerable. They spend heavily on our politicians, which always helps, and are also viewed as crucial to our economy. That protects them. If their banks go south, our economy could go with them. (The poor have no such argument.) So except for a couple of criminal outliers, such as Ponzi-scheme master Bernard Madoff, financiers don't get arrested. As a group, they made it through the 2008 market crash practically unscathed. What could ever burn them now?

My point is that police make choices about where they direct their attention. Today they focus almost exclusively on the poor. That's their heritage, and their mission, as they understand it. And now data scientists are stitching this status quo of the social order into models, like PredPol, that hold ever-greater sway over our lives.

The result is that while PredPol delivers a perfectly useful and even high-minded software tool, it is also a do-it-yourself WMD. In

this sense, PredPol, even with the best of intentions, empowers police departments to zero in on the poor, stopping more of them, arresting a portion of those, and sending a subgroup to prison. And the police chiefs, in many cases, if not most, think that they're taking the only sensible route to combating crime. That's where it is, they say, pointing to the highlighted ghetto on the map. And now they have cutting-edge technology (powered by Big Data) reinforcing their position there, while adding precision and "science" to the process.

The result is that we criminalize poverty, believing all the while that our tools are not only scientific but fair.

One weekend in the spring of 2011, I attended a data "hackathon" in New York City. The goal of such events is to bring together hackers, nerds, mathematicians, and software geeks and to mobilize this brainpower to shine light on the digital systems that wield so much power in our lives. I was paired up with the New York Civil Liberties Union, and our job was to break out the data on one of the NYPD's major anticrime policies, so-called stop, question, and frisk. Known simply as stop and frisk to most people, the practice had drastically increased in the data-driven age of CompStat.

The police regarded stop and frisk as a filtering device for crime. The idea is simple. Police officers stop people who look suspicious to them. It could be the way they're walking or dressed, or their tattoos. The police talk to them and size them up, often while they're spread-eagled against a wall or the hood of a car. They ask for their ID, and they frisk them. Stop enough people, the thinking goes, and you'll no doubt stop loads of petty crimes, and perhaps some big ones. The policy, implemented by Mayor Michael Bloomberg's administration, had loads of public support. Over the previous decade, the number of stops had risen by 600 percent, to nearly seven hundred thousand incidents. The great majority of those stopped were innocent. For them, these encounters were highly unpleasant, even infuriating. Yet many in the public associated the program with the sharp decline of crime in the city. New York, many felt, was safer. And statistics indicated as much. Homicides, which had reached 2,245 in 1990, were down to 515 (and would drop

below 400 by 2014).

Everyone knew that an outsized proportion of the people the police stopped were young, dark-skinned men. But how many did they stop? And how often did these encounters lead to arrests or stop crimes? While this information was technically public, much of it was stored in a database that was hard to access. The software didn't work on our computers or flow into Excel spreadsheets. Our job at the hackathon was to break open that program and free the data so that we could all analyze the nature and effectiveness of the stop-and-frisk program.

What we found, to no great surprise, was that an overwhelming majority of these encounters—about 85 percent—involved young African American or Latino men. In certain neighborhoods, many of them were stopped repeatedly. Only 0.1 percent, or one of one thousand stopped, was linked in any way to a violent crime. Yet this filter captured many others for lesser crimes, from drug possession to underage drinking, that might have otherwise gone undiscovered. Some of the targets, as you might expect, got angry, and a good number of those found themselves charged with resisting arrest.

The NYCLU sued the Bloomberg administration, charging that the stop-and-frisk policy was racist. It was an example of uneven policing, one that pushed more minorities into the criminal justice system and into prison. Black men, they argued, were six times more likely to be incarcerated than white men and twenty-one times more likely to be killed by police, at least according to the available data (which is famously underreported).

Stop and frisk isn't exactly a WMD, because it relies on human judgment and is not formalized into an algorithm. But it is built upon a simple and destructive calculation. If police stop one thousand people in certain neighborhoods, they'll uncover, on average, one significant suspect and lots of smaller ones. This isn't so different from the long-shot calculations used by predatory advertisers or spammers. Even when the hit ratio is miniscule, if you give yourself enough chances you'll reach your target. And that helps to explain why the program grew so dramatically under Bloomberg's watch. If stopping six times as many people led to six times the number of arrests, the inconvenience and harassment suffered by thousands upon thousands of innocent people was

justified. Weren't *they* interested in stopping crime?

Aspects of stop and frisk were similar to WMDs, though. For example, it had a nasty feedback loop. It ensnared thousands of black and Latino men, many of them for committing the petty crimes and misdemeanors that go on in college frats, unpunished, every Saturday night. But while the great majority of university students were free to sleep off their excesses, the victims of stop and frisk were booked, and some of them dispatched to the hell that is Rikers Island. What's more, each arrest created new data, further justifying the policy.

As stop and frisk grew, the venerable legal concept of probable cause was rendered virtually meaningless, because police were hunting not only people who might have already committed a crime but also those who might commit one in the future. Sometimes, no doubt, they accomplished this goal. By arresting a young man whose suspicious bulge turned out to be an unregistered gun, they might be saving the neighborhood from a murder or armed robbery, or even a series of them. Or maybe not. Whatever the case, there was a logic to stop and frisk, and many found it persuasive.

But was the policy constitutional? In August of 2013, federal judge Shira A. Scheindlin ruled that it was not. She said officers routinely "stopped blacks and Hispanics who would not have been stopped if they were white." Stop and frisk, she wrote, ran afoul of the Fourth Amendment, which protects against unreasonable searches and seizures by the government, and it also failed to provide the equal protection guaranteed by the Fourteenth Amendment. She called for broad reforms to the practice, including increased use of body cameras on patrolling policemen. This would help establish probable cause—or the lack of it—and remove some of the opacity from the stop-and-frisk model. But it would do nothing to address the issue of uneven policing.

While looking at WMDs, we're often faced with a choice between fairness and efficacy. Our legal traditions lean strongly toward fairness. The Constitution, for example, presumes innocence and is engineered to value it. From a modeler's perspective, the presumption of innocence is a constraint, and the result is that some guilty people go free, especially those who can afford good lawyers. Even those found guilty have the right to appeal their

verdict, which chews up time and resources. So the system sacrifices enormous efficiencies for the promise of fairness. The Constitution's implicit judgment is that freeing someone who may well have committed a crime, for lack of evidence, poses less of a danger to our society than jailing or executing an innocent person.

WMDs, by contrast, tend to favor efficiency. By their very nature, they feed on data that can be measured and counted. But fairness is squishy and hard to quantify. It is a concept. And computers, for all of their advances in language and logic, still struggle mightily with concepts. They "understand" beauty only as a word associated with the Grand Canyon, ocean sunsets, and grooming tips in *Vogue* magazine. They try in vain to measure "friendship" by counting likes and connections on Facebook. And the concept of fairness utterly escapes them. Programmers don't know how to code for it, and few of their bosses ask them to.

So fairness isn't calculated into WMDs. And the result is massive, industrial production of *unfairness*. If you think of a WMD as a factory, unfairness is the black stuff belching out of the smoke stacks. It's an emission, a toxic one.

The question is whether we as a society are willing to sacrifice a bit of efficiency in the interest of fairness. Should we handicap the models, leaving certain data out? It's possible, for example, that adding gigabytes of data about antisocial behavior might help PredPol predict the mapping coordinates for serious crimes. But this comes at the cost of a nasty feedback loop. So I'd argue that we should discard the data.

It's a tough case to make, similar in many ways to the battles over wiretapping by the National Security Agency. Advocates of the snooping argue that it's important for our safety. And those running our vast national security apparatus will keep pushing for more information to fulfill their mission. They'll continue to encroach on people's privacy until they get the message that they must find a way to do their job within the bounds of the Constitution. It might be harder, but it's necessary.

The other issue is equality. Would society be so willing to sacrifice the concept of probable cause if everyone had to endure the harassment and indignities of stop and frisk? Chicago police have

their own stop-and-frisk program. In the name of fairness, what if they sent a bunch of patrollers into the city's exclusive Gold Coast? Maybe they'd arrest joggers for jaywalking from the park across W. North Boulevard or crack down on poodle pooping along Lakeshore Drive. This heightened police presence would probably pick up more drunk drivers and perhaps uncover a few cases of insurance fraud, spousal abuse, or racketeering. Occasionally, just to give everyone a taste of the unvarnished experience, the cops might throw wealthy citizens on the trunks of their cruisers, wrench their arms, and snap on the handcuffs, perhaps while swearing and calling them hateful names.

In time, this focus on the Gold Coast would create data. It would describe an increase in crime there, which would draw even more police into the fray. This would no doubt lead to growing anger and confrontations. I picture a double parker talking back to police, refusing to get out of his Mercedes, and finding himself facing charges for resisting arrest. Yet another Gold Coast crime.

This may sound less than serious. But a crucial part of justice is equality. And that means, among many other things, experiencing criminal justice equally. People who favor policies like stop and frisk should experience it themselves. Justice cannot just be something that one part of society inflicts upon the other.

The noxious effects of uneven policing, whether from stop and frisk or predictive models like PredPol, do not end when the accused are arrested and booked in the criminal justice system. Once there, many of them confront another WMD that I discussed in [chapter 1](#), the recidivism model used for sentencing guidelines. The biased data from uneven policing funnels right into this model. Judges then look to this supposedly scientific analysis, crystallized into a single risk score. And those who take this score seriously have reason to give longer sentences to prisoners who appear to pose a higher risk of committing other crimes.

And why are nonwhite prisoners from poor neighborhoods more likely to commit crimes? According to the data inputs for the recidivism models, it's because they're more likely to be jobless, lack a high school diploma, and have had previous run-ins with the law. And their friends have, too.

Another way of looking at the same data, though, is that these prisoners live in poor neighborhoods with terrible schools and scant opportunities. And they're highly policed. So the chance that an ex-convict returning to that neighborhood will have another brush with the law is no doubt larger than that of a tax fraudster who is released into a leafy suburb. In this system, the poor and nonwhite are punished more for being who they are and living where they live.

What's more, for supposedly scientific systems, the recidivism models are logically flawed. The unquestioned assumption is that locking away "high-risk" prisoners for more time makes society safer. It is true, of course, that prisoners don't commit crimes against society while behind bars. But is it possible that their time in prison has an effect on their behavior once they step out? Is there a chance that years in a brutal environment surrounded by felons might make them more likely, and not less, to commit another crime? Such a finding would undermine the very basis of the recidivism sentencing guidelines. But prison systems, which are awash in data, do not carry out this highly important research. All too often they use data to justify the workings of the system but not to question or improve the system.

Compare this attitude to the one found at Amazon.com. The giant retailer, like the criminal justice system, is highly focused on a form of recidivism. But Amazon's goal is the opposite. It wants people to come back again and again to buy. Its software system targets recidivism and encourages it.

Now, if Amazon operated like the justice system, it would start by scoring shoppers as potential recidivists. Maybe more of them live in certain area codes or have college degrees. In this case, Amazon would market more to these people, perhaps offering them discounts, and if the marketing worked, those with high recidivist scores would come back to shop more. If viewed superficially, the results would appear to corroborate Amazon's scoring system.

But unlike the WMDs in criminal justice, Amazon does not settle for such glib correlations. The company runs a data laboratory. And if it wants to find out what drives shopping recidivism, it carries out research. Its data scientists don't just study zip codes and education levels. They also inspect people's experience within the Amazon

ecosystem. They might start by looking at the patterns of all the people who shopped once or twice at Amazon and never returned. Did they have trouble at checkout? Did their packages arrive on time? Did a higher percentage of them post a bad review? The questions go on and on, because the future of the company hinges upon a system that learns continually, one that figures out what makes customers tick.

If I had a chance to be a data scientist for the justice system, I would do my best to dig deeply to learn what goes on inside those prisons and what impact those experiences might have on prisoners' behavior. I'd first look into solitary confinement. Hundreds of thousands of prisoners are kept for twenty-three hours a day in these prisons within prisons, most of them no bigger than a horse stall. Researchers have found that time in solitary produces deep feelings of hopelessness and despair. Could that have any impact on recidivism? That's a test I'd love to run, but I'm not sure the data is even collected.

How about rape? In *Unfair: The New Science of Criminal Injustice*, Adam Benforado writes that certain types of prisoners are targeted for rape in prisons. The young and small of stature are especially vulnerable, as are the mentally disabled. Some of these people live for years as sex slaves. It's another important topic for analysis that anyone with the relevant data and expertise could work out, but prison systems have thus far been uninterested in cataloging the long-term effects of this abuse.

A serious scientist would also search for positive signals from the prison experience. What's the impact of more sunlight, more sports, better food, literacy training? Maybe these factors will improve convicts' behavior after they go free. More likely, they'll have varying impact. A serious justice system research program would delve into the effects of each of these elements, how they work together, and which people they're most likely to help. The goal, if data were used constructively, would be to optimize prisons—much the way companies like Amazon optimize websites or supply chains—for the benefit of both the prisoners and society at large.

But prisons have every incentive to avoid this data-driven approach. The PR risks are too great—no city wants to be the subject of a scathing report in the *New York Times*. And, of course,

there's big money riding on the overcrowded prison system. Privately run prisons, which house only 10 percent of the incarcerated population, are a \$5 billion industry. Like airlines, the private prisons make profits only when running at high capacity. Too much poking and prodding might threaten that income source.

So instead of analyzing prisons and optimizing them, we deal with them as black boxes. Prisoners go in and disappear from our view. Nastiness no doubt occurs, but behind thick walls. What goes on in there? Don't ask. The current models stubbornly stick to the dubious and unquestioned hypothesis that more prison time for supposedly high-risk prisoners makes us safer. And if studies appear to upend that logic, they can be easily ignored.

And this is precisely what happens. Consider a recidivism study by Michigan economics professor Michael Mueller-Smith. After studying 2.6 million criminal court records in Harris County, Texas, he concluded that the longer inmates in Harris County, Texas, spent locked up, the greater the chance that they would fail to find employment upon release, would require food stamps and other public assistance, and would commit further crimes. But to turn those conclusions into smart policy and better justice, politicians will have to take a stand on behalf of a feared minority that many (if not most) voters would much prefer to ignore. It's a tough sell.

■ ■ ■

Stop and frisk may seem intrusive and unfair, but in short time it will also be viewed as primitive. That's because police are bringing back tools and techniques from the global campaign against terrorism and focusing them on local crime fighting. In San Diego, for example, police are not only asking the people they stop for identification, or frisking them. On occasion, they also take photos of them with iPads and send them to a cloud-based facial recognition service, which matches them against a database of criminals and suspects. According to a report in the *New York Times*, San Diego police used this facial recognition program on 20,600 people between 2011 and 2015. They also probed many of them with mouth swabs to harvest DNA.

Advances in facial recognition technology will soon allow for

much broader surveillance. Officials in Boston, for example, were considering using security cameras to scan thousands of faces at outdoor concerts. This data would be uploaded to a service that could match each face against a million others per second. In the end, officials decided against it. Concern for privacy, on that occasion, trumped efficiency. But this won't always be the case.

As technology advances, we're sure to see a dramatic growth of surveillance. The good news, if you want to call it that, is that once thousands of security cameras in our cities and towns are sending up our images for analysis, police won't have to discriminate as much. And the technology will no doubt be useful for tracking down suspects, as happened in the Boston Marathon bombing. But it means that we'll all be subject to a digital form of stop and frisk, our faces matched against databases of known criminals and terrorists.

The focus then may well shift toward spotting *potential* lawbreakers—not just neighborhoods or squares on a map but individuals. These preemptive campaigns, already well established in the fight against terrorism, are a breeding ground for WMDs.

In 2009, the Chicago Police Department received a \$2 million grant from the National Institute of Justice to develop a predictive program for crime. The theory behind Chicago's winning application was that with enough research and data they might be able to demonstrate that the spread of crime, like epidemics, follows certain patterns. It can be predicted and, hopefully, prevented.

The scientific leader of the Chicago initiative was Miles Wernick, the director of the Medical Imaging Research Center at the Illinois Institute of Technology (IIT). Decades earlier, Wernick had helped the US military analyze data to pick out battlefield targets. He had since moved to medical data analysis, including the progression of dementia. But like most data scientists, he didn't see his expertise as tethered to a specific industry. He spotted patterns. And his focus in Chicago would be the patterns of crime, and of criminals.

The early efforts of Wernick's team focused on singling out hot spots for crime, much as PredPol does. But the Chicago team went much further. They developed a list of the approximately four hundred people most likely to commit a violent crime. And it ranked them on the probability that they would be involved in a

homicide.

One of the people on the list, a twenty-two-year-old high school dropout named Robert McDaniel, answered his door one summer day in 2013 and found himself facing a police officer. McDaniel later told the *Chicago Tribune* that he had no history of gun violations and had never been charged with a violent crime. Like most of the young men in Austin, his dangerous West Side neighborhood, McDaniel had had brushes with the law, and he knew plenty of people caught up in the criminal justice system. The policewoman, he said, told him that the force had its eye on him and to watch out.

Part of the analysis that led police to McDaniel involved his social network. He knew criminals. And there is no denying that people are statistically more likely than not to behave like the people they spend time with. Facebook, for example, has found that friends who communicate often are far more likely to click on the same advertisement. Birds of a feather, statistically speaking, *do* fly together.

And to be fair to Chicago police, they're not arresting people like Robert McDaniel, at least not yet. The goal of the police in this exercise is to save lives. If the four hundred people who appear most likely to commit violent crimes receive a knock on the door and a warning, maybe some of them will think twice before packing a gun.

But let's consider McDaniel's case in terms of fairness. He happened to grow up in a poor and dangerous neighborhood. In this, he was unlucky. He has been surrounded by crime, and many of his acquaintances have gotten caught up in it. And largely because of these circumstances—and not his own actions—he has been deemed dangerous. Now the police have their eye on him. And if he behaves foolishly, as millions of other Americans do on a regular basis, if he buys drugs or gets into a barroom fight or carries an unregistered handgun, the full force of the law will fall down on him, and probably much harder than it would on most of us. After all, he's been warned.

I would argue that the model that led police to Robert McDaniel's door has the wrong objective. Instead of simply trying to eradicate crimes, police should be attempting to build relationships in the neighborhood. This was one of the pillars of the original “broken-

windows” study. The cops were on foot, talking to people, trying to help them uphold their own community standards. But that objective, in many cases, has been lost, steamrolled by models that equate arrests with safety.

This isn’t the case everywhere. I recently visited Camden, New Jersey, which was the murder capital of the country in 2011. I found that the police department in Camden, rebuilt and placed under state control in 2012, had a dual mandate: lowering crime and engendering community trust. If building trust is the objective, an arrest may well become a last resort, not the first. This more empathetic approach could lead to warmer relations between the police and the policed, and fewer of the tragedies we’ve seen in recent years—the police killings of young black men and the riots that follow them.

From a mathematical point of view, however, trust is hard to quantify. That’s a challenge for people building models. Sadly, it’s far simpler to keep counting arrests, to build models that assume we’re birds of a feather and treat us as such. Innocent people surrounded by criminals get treated badly, and criminals surrounded by a law-abiding public get a pass. And because of the strong correlation between poverty and reported crime, the poor continue to get caught up in these digital dragnets. The rest of us barely have to think about them.
